# Introduction

# Introduction

## Definition of feature:

- Piece of information that is useful to solve a given task
- Interesting part of the image

## Types of features:

- **Global:** global properties of the whole image
  - Mean grey level, mean colour, main colours, histogram
- **Local:** properties of a part of the image with their own entity
  - Points, edges, regions

# Introduction

GLOBAL

LOCAL

# Introduction

- **Local features:**
  - Part of an image that differs from its surroundings.
  - They are associated to a change in a certain property (intensity, color, texture)
  - Examples:
    - Points (corners, interest points)
    - Edges, ridges
    - Small regions (blobs)

# Introduction

- How can we find local features?
  - Feature detection/extraction algorithms
- Detection/Extraction: locate the position of the feature
- Description (Unit 7): measures that are taken from the detected feature that allow us to distinguish it or compare with others

# Introduction

- Why do we use features?
  - They have been used with success in several disciplines and applications:
    - Edge detection associated to roads in aerial images
    - Quality control
    - Polyp Detection
  - Interest points play a key role for certain Applications:
    - Tracking
    - 3D reconstruction
  - They are a first step to achieve a robust image representation:
    - Object recognition
    - Scene classification
    - Texture analysis
    - Image search

# Introduction

- Ideal properties:
  - Repetability:
    - Invariance to transformations
    - Robustness
  - Differentiation (highly different from another)
  - Precise localization
  - Enough points for the needed task
  - Efficient
- Scale: very important factor to achieve robustness, invariance and precision. Allows us to work with different images at several distances.

# Introduction

# Corner Detection

# Corner Detection

**Plain region**  
No changes in all  
directions

**Edge**  
No change in edge  
direction

**Corner**  
Significant changes in  
all directions

# Corner Detection

- Harris (1988): Based on the analysis of the 2D structural tensor (second derivative matrix, second moment matrix)
- SUSAN (Smallest Univalued Segment Assimilating Nucleus): morphologic focus
- Harris-Laplace: Use of Harris for a first detection; scale is fixed using laplacian
- Harris-Affine: Use of Harris-Laplace; then it tries to estimate the most affine shape (with an ellipse that is later normalized to a circle)

# Corner Detection: Harris

- In an image intensity corner, intensity changes significantly in all directions.
- Here we are focused in intensity changes in a local window.
- We use SSD: sum of squared differences

$$S(x, y) = \sum_u \sum_v w(u, v) (I(u + x, v + y) - I(u, v))^2$$

Diagram illustrating the components of the Harris corner detection formula:

- window**: Points to the summation indices  $u$  and  $v$ .
- Shifted intensities**: Points to the term  $I(u + x, v + y)$ .
- intensity**: Points to the term  $I(u, v)$ .

Window function  $w(u, v) =$

1 inside , 0 outside

gaussian

# Corner Detection: Harris

Shifted intensity is approximated using a Taylor Expansion:

$$I(u + x, v + y) \approx I(u, v) + I_x(u, v)x + I_y(u, v)y$$

So, at the end:

$$S(x, y) \approx \sum_u \sum_v w(u, v) (I_x(u, v)x + I_y(u, v)y)^2,$$

We can write this in matrix format as:

$$S(x, y) \approx \begin{pmatrix} x & y \end{pmatrix} A \begin{pmatrix} x \\ y \end{pmatrix},$$

, where A is the 2D structural tensor

$$A = \sum_u \sum_v w(u, v) \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix} = \begin{bmatrix} \langle I_x^2 \rangle & \langle I_x I_y \rangle \\ \langle I_x I_y \rangle & \langle I_y^2 \rangle \end{bmatrix}$$

# Corner Detection: Harris

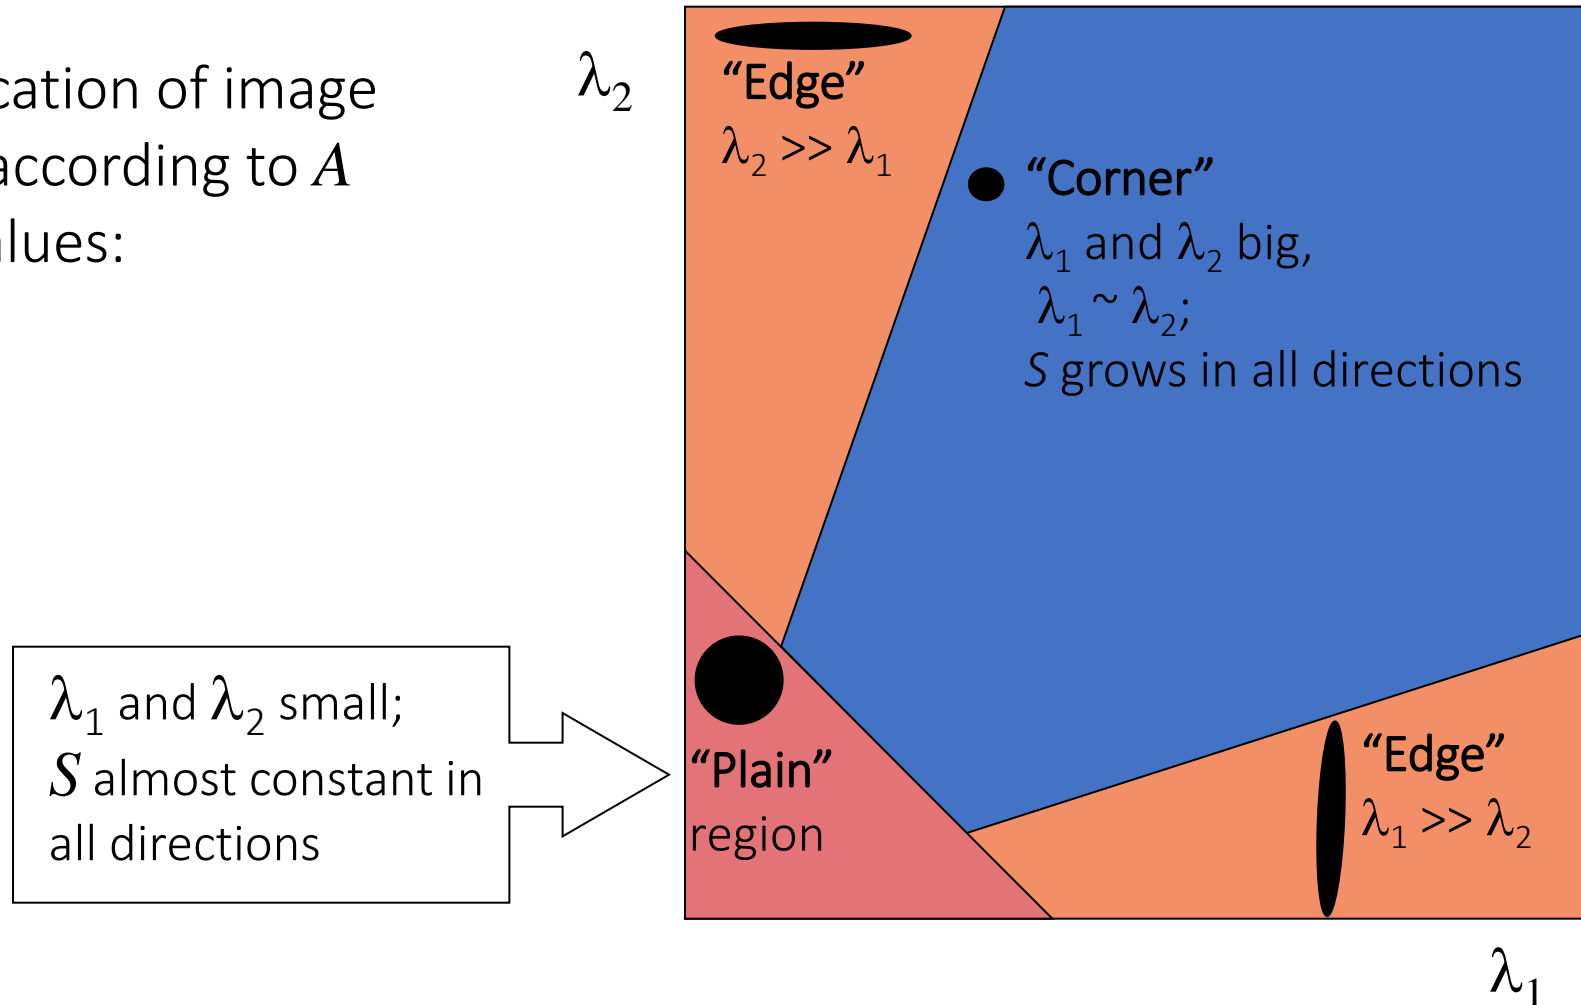

We change the problem of examining intensity changes due to translations to analyze the behaviour of matrix  $A \rightarrow$  analysis of eigenvalues

$\lambda_1, \lambda_2$  eigenvalues of  $A$

# Corner Detection: Harris

Classification of image points according to  $A$  eigenvalues:

# Corner Detection: Harris

Response function at corners ( $R$ ):

$$R = \det(A) - k (\text{trace } A)^2$$

$$R = \lambda_1 \lambda_2 - k (\lambda_1 + \lambda_2)^2$$

where  $k$  is a constant value (empiric)  $k = [0.04, 0.06]$

# Corner Detection: Harris

- $R$  depends only of  $A$  eigenvalues
- $R$  is big at corners
- $R$  is negative with high value at corners
- $|R|$  is small at plain regions

# Corner Detection: Harris

- First derivatives at an image point  $(u,v)$ :

$$I_x(u,v) = \frac{\partial I}{\partial x}(u,v)$$

$$I_y(u,v) = \frac{\partial I}{\partial y}(u,v)$$

- We can compute:

$$A(u,v) = I_x^2(u,v),$$

$$B(u,v) = I_x I_y(u,v),$$

$$C(u,v) = I_y^2(u,v)$$

- Local structure matrix ( $M$ )  
[a.k.a.  $A$ ]

$$M = \begin{pmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{pmatrix} = \begin{pmatrix} A & C \\ C & B \end{pmatrix}$$

- Smoothing with a gaussian ( $G$ )

$$\bar{M} = \begin{pmatrix} A * G & C * G \\ C * G & B * G \end{pmatrix} = \begin{pmatrix} \bar{A} & \bar{C} \\ \bar{C} & \bar{B} \end{pmatrix}$$

# Corner Detection: Harris

- Diagonal of  $\overline{M}$

$$\overline{M} = \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix}$$

- Where  $\lambda_1, \lambda_2$  are the eigenvalues of  $\overline{M}$  defined by:

$$\frac{1}{2} \left( \overline{A} + \overline{B} \pm \sqrt{\overline{A}^2 - 2\overline{A}\overline{B} + \overline{B}^2 + 4\overline{C}^2} \right)$$

- Describes a point according to eigenvalues, using corners response function

$$R = \lambda_1 \lambda_2 - k (\lambda_1 + \lambda_2)^2$$

- A good corner has big changes of intensity in all directions  $\rightarrow$  R should be big and positive.

# Corner Detection: Harris

Original

# Corner Detection: Harris

$R$

# Corner Detection: Harris

Points with  $R > \text{threshold}$

# Corner Detection: Harris

$R$  local maxima

# Corner Detection: Harris

Final result

# Corner Detection: Harris-Laplace

- Properties:

- Rotation invariant:

- Partial invariance to affine intensity changes (derivatives):

- Invariance to shifts in intensity  $I \rightarrow I+b$
    - Contrast change:  $I \rightarrow aI$

# Corner Detection: Harris-Laplace

- Combines Harris with a gaussian scale-space.
- We use gaussian Windows with predetermined scales
- We choose the scale that maximizes LoG in this range

- We obtain both the corners and the scale in which it is better represented

# Corner Detection: Harris-Affine

- Initial detection using Harris-Laplace
- Affine shape estimated using 2D structure matrix
- Normalize affine regions to a circular shape
- Detect new corner position and scales in the previous image
- If eigenvalues change, go back to point 2

# Harris Corner Detector in OpenCV

```
import numpy as np
import cv2 as cv
filename = 'chessboard.png'
img = cv.imread(filename)
gray = cv.cvtColor(img,cv.COLOR_BGR2GRAY)
gray = np.float32(gray)
dst = cv.cornerHarris(gray,2,3,0.04)
dst = cv.dilate(dst,None)
# Threshold for an optimal value, it may vary depending on the image.
img[dst>0.01*dst.max()]=[0,0,255]
cv.imshow('dst',img)
if cv.waitKey(0) & 0xff == 27:
    cv.destroyAllWindows()
```
